```

Three different statistical tests

1) t-test (Sex) [Type: mean comparison] -> RQ3

2) ANOVA (Race) [Type: mean comparison] -> RQ3

3) OLS Regression [Type: regression] -> RQ1/RQ2

Each includes: results + analysis + conclusion tied to RQs

```r
# TEST 1 (RQ3): Two-sample t-test comparing mean rates by Sex

# Descriptives
sex_means <- state_year_sex %>%
  group_by(sex) %>%
  summarise(
    mean_rate = mean(rate_per_100k, na.rm = TRUE),
    sd_rate   = sd(rate_per_100k, na.rm = TRUE),
    n         = n(),
    .groups = "drop"
  )
kable(sex_means, digits = 2, caption = "Descriptives: state-year suicide rates by sex")
```

Table 1: Descriptives: state-year suicide rates by sex

sex	mean_rate	sd_rate	n
Female	1.64	2.65	924
Male	4.38	2.50	1102

```r
# Test
t_sex <- t.test(rate_per_100k ~ sex, data = state_year_sex)
print(t_sex)
```

```
Welch Two Sample t-test
```

data: rate_per_100k by sex t = -23.743, df = 1918.8, p-value < 2.2e-16 alternative hypothesis: true difference in means between group Female and group Male is not equal to 0 95 percent confidence interval: -2.961724 -2.509772 sample estimates: mean in group Female mean in group Male 1.639507 4.375255

```r
# Analysis + conclusion
cat("\n**Analysis (t-test, RQ3):** This two-sample t-test evaluates whether the mean state-year suicide
```

Analysis (t-test, RQ3): This two-sample t-test evaluates whether the mean state-year suicide mortality rate differs between males and females. A statistically significant p-value indicates evidence of a difference in average rates by sex in this dataset.

```
if (t_sex$p.value < 0.05) {
  cat("**Conclusion (t-test, RQ3):** The test is statistically significant (p < 0.05), suggesting mean s
} else {
  cat("**Conclusion (t-test, RQ3):** The test is not statistically significant (p >= 0.05), suggesting r
}
```

Conclusion (t-test, RQ3): The test is statistically significant ($p < 0.05$), suggesting mean suicide mortality rates differ by sex. This is consistent with expectations that male rates are higher on average.

```
# TEST 2 (RQ3): One-way ANOVA comparing mean rates across Race categories

# Descriptives
race_means <- state_year_race %>%
  group_by(race) %>%
  summarise(
    mean_rate = mean(rate_per_100k, na.rm = TRUE),

cat("\n**Analysis (Poisson regression, RQ1/RQ2):** Poisson regression models death counts while account
```

Analysis (Poisson regression, RQ1/RQ2): Poisson regression models death counts while accounting for population exposure using an offset. exp(beta_year) is the incidence rate ratio (IRR), interpreted as the multiplicative change in expected deaths per year (holding state constant and adjusting for population).

```
if (!is.na(p_year_pois) && p_year_pois < 0.05) {
  cat(paste0("**Conclusion (Poisson regression, RQ1/RQ2):** The year effect is statistically significan
             ", meaning expected deaths increase by about ", round((irr - 1) * 100, 2), "% per year (sta
} else {
  cat("**Conclusion (Poisson regression, RQ1/RQ2):** The year effect is not statistically significant (
}
```

Conclusion (Poisson regression, RQ1/RQ2): The year effect is statistically significant ($p < 0.05$). IRR approximately 1.0126, meaning expected deaths increase by about 1.26% per year (state fixed, population-adjusted).

```
cat("**Model choice justification:** If overdispersion is present (variance >> mean), a Negative Binomia
```

Model choice justification: If overdispersion is present (variance » mean), a Negative Binomial model is more appropriate than Poisson. I will check dispersion diagnostics before selecting Poisson vs Negative Binomial for the final model.
